Recommender systems (purchase)

- Given data from user buying behaviors
 - User profiles, interests, browsing behavior, buying behavior, and ratings about various items
- Leverage such data to make **recommendations** to customers about possible buying interests

Recommender systems (general)

- Given data from user interests
 - User profiles, interests, browsing behavior, item interaction behavior, ratings about various items
- Leverage such data to make **recommendations** to users about further **interesting** items

STEAM®

Utility matrix

- For n users and d items, there is a **matrix D of utility values**
 - **The utility value** for a user-item pair could correspond, e.g., to buying behavior or ratings of the user for the item
 - Typically, **a small subset of the utility values are known**

Utility matrix (ratings-based, positive preference)

| | GLADIATOR | GODFATHER | BEN-HUR | GOODFELLAS | SCARFACE | SPARTACUS |
|-------|-----------|-----------|---------|------------|----------|-----------|
| U_1 | 1 | | | 5 | | 2 |
| U_2 | | 5 | | | 4 | |
| U_3 | 5 | 3 | | 1 | | |
| U_4 | | | 3 | | | 4 |
| U_5 | | | | 3 | 5 | |
| U_6 | 5 | | 4 | | | |

(a) Ratings-based utility

| | GLADIATOR | GODFATHER | BEN-HUR | GOODFELLAS | SCARFACE | SPARTACUS |
|-------|-----------|-----------|---------|------------|----------|-----------|
| U_1 | 1 | | | 1 | | 1 |
| U_2 | | 1 | | | 1 | |
| U_3 | 1 | 1 | | 1 | | |
| U_4 | | | 1 | | | 1 |
| U_5 | | | | 1 | 1 | |
| U_6 | 1 | | 1 | | | |

(b) Positive-preference utility

Types of utility

- **Explicit:** we ask users to rate items

- **Implicit:** we take watching/consuming/buying behavior as a positive signal, skip/hide as negative

Sources for a recommendation

- Content-based recommendation
 - Users and items are associated with features
 - Features are matched to infer interest
- Interaction-based recommendations
 - Leverage user preferences in the form of ratings or other behavior
 - Recommend through similarity or latent factors

THE COLD START PROBLEM

New items have no ratings
and
New users have no history

Content-based recommendations

General idea of content-based recommendations

- Movies: recommend other movies with **same** director, actor, genre, as viewed ones
- Products: recommend other products in **same** category, brand, color, as purchased ones

Creating a recommendation

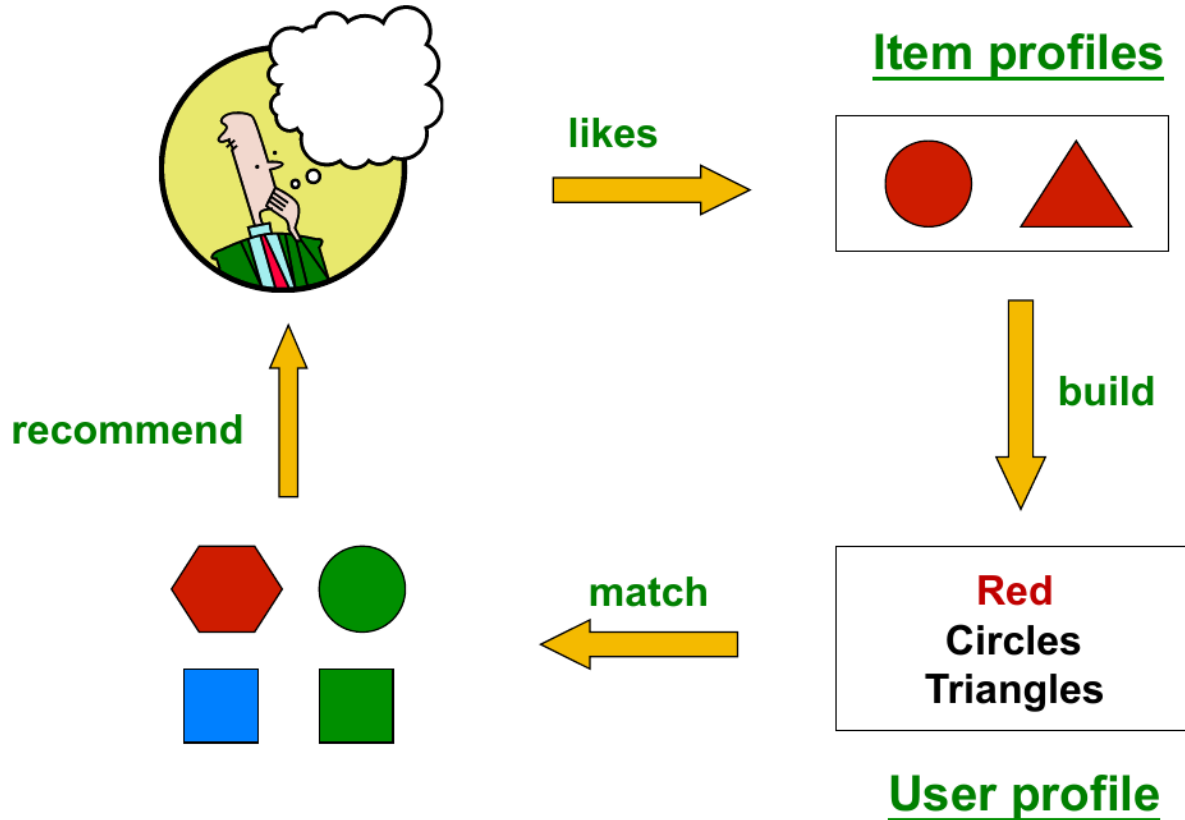

- User is associated with some documents that describe his/her interests
 - Specified demographic profile
 - Specified interests at registration time
 - Descriptions of the items bought
- Items are also associated with semi-structured descriptions

JBL GO lleva el sonido de calidad JBL a todas partes. GO es su solución de altavoz todo en uno y reproduce música en tiempo real vía Bluetooth desde smartphones y tabletas, gracias a su batería recargable. También cuenta con un práctico manos libres.

| | |
|-------------------------|----------------|
| Potencia | 3 W |
| Respuesta de Frecuencia | 180Hz – 20 kHz |
| Tipo de altavoz | Portátil |
| Amplificador de sonido | Integrado |

Creating a recommendation (cont.)

Possible recommendation methods

- **If no utility matrix is available**
 - k-nearest neighbor approach
 - Find the top-k items that are closest to the user (when items and users can be represented in the same space, e.g., dating apps)
 - The cosine similarity with tf-idf can be used
- **If a utility matrix is available**
 - Classification-based approach: training documents are those for which the user has specified utility, labels are utility values
 - Regression-based approach in the case of ratings
- Limitations: depends on the quality of the features

Example: regression-based approach for content-based recommendation

| Movie | Adventure | Action | Science-Fiction | Drama | Crime | Thriller | | User 1 | User 2 |
|---------------------|-----------|--------|-----------------|-------|-------|----------|--|--------|--------|
| Star Wars IV | 1 | 1 | 1 | 0 | 0 | 0 | | 1 | -1 |
| Saving Private Ryan | 0 | 0 | 0 | 1 | 0 | 0 | | | |
| American Beauty | 0 | 0 | 0 | 1 | 0 | 0 | | | |
| City of Gold | 0 | 0 | 0 | 1 | 1 | 0 | | -1 | 1 |
| Interstellar | 0 | 0 | 1 | 1 | 0 | 0 | | 1 | |
| The Matrix | 1 | 1 | 1 | 0 | 0 | 1 | | | 1 |

...

We would do two regressions: one for the ratings of user 1 and another for user 2.

How many rated movies would we need, as a minimum, to be able to do this?

Pros and Cons of content-based recommendations

- Pros:
 - No cold-start problem if no utility needed
 - Able to recommend to users with very particular tastes
 - Able to recommend new and obscure items
 - Able to provide explanations that are easily understandable

Pros and Cons of content-based recommendations

- **Cons:**
 - Finding the correct features might be hard
 - Recommending for new users still challenging if user features are different from item features
 - Overspecialization/"bubble": might reinforce user interests
 - Does not exploit ratings of other users!

Interaction-based recommendations

Missing-value estimation/completion

- The matrix is extremely **large** and **sparse**

$$M = \begin{bmatrix} \blacksquare & & \blacksquare & & \blacksquare & & \\ & \blacksquare & & \blacksquare & \blacksquare & & \blacksquare \\ \blacksquare & & & \blacksquare & & \blacksquare & \\ & & \blacksquare & & \blacksquare & & \\ & \blacksquare & & \blacksquare & & & \\ & & & & & & \blacksquare \end{bmatrix} \in \mathbb{R}^{n \times d}$$

Only black squares have non-zero values.

Types of algorithms

- Neighborhood-Based Methods
 - User-Based or Item-Based Similarity with Ratings
- Graph-Based Methods
- Clustering Methods
 - Adapting k-Means Clustering or Adapting Co-Clustering
- Latent Factor Models
 - Matrix Factorization, e.g., Singular Value Decomposition

User-based similarity with ratings

- Let $I_{u,v}$ be common ratings between two users
- Similarity: Pearson correlation coefficient

$$\text{sim}(u, v) = \frac{\sum_{i \in I_{u,v}} (u_i - \hat{u}) \cdot (v_i - \hat{v})}{\sqrt{\sum_{i \in I_{u,v}} (u_i - \hat{u})^2 \cdot \sum_{i \in I_{u,v}} (v_i - \hat{v})^2}}$$

$$\hat{u} = \frac{1}{|u|} \sum_{i=1}^{|u|} u_i \quad \hat{v} = \frac{1}{|v|} \sum_{i=1}^{|v|} v_i$$

Note: averages are taken over all elements, not only ones in common

User-based similarity with ratings (cont.)

$$\text{sim}(u, v) = \frac{\sum_{i \in I_{u,v}} (u_i - \hat{u}) \cdot (v_i - \hat{v})}{\sqrt{\sum_{i \in I_{u,v}} (u_i - \hat{u})^2 \cdot \sum_{i \in I_{u,v}} (v_i - \hat{v})^2}}$$

- Score of recommendation

$$\text{score}(u, i) = \hat{u} + \frac{\sum_{v: v_i \neq \text{NULL}} \text{sim}(v, u) \cdot (v_i - \hat{v})}{\sum_{v: I_{u,v} \neq \emptyset} |\text{sim}(v, u)|}$$

Note: for efficiency one can take only the most similar users

Try it!

A red arrow labeled 'u' points to the fifth user avatar.

| | | | | | |
|---|---|---|---|---|---|
| 2 | | | 4 | 5 | |
| 5 | | 4 | | | 1 |
| | | 5 | | 2 | |
| | 1 | | 5 | | 4 |
| | | 4 | | | 2 |
| 4 | 5 | | 1 | | |

1. Compute $\text{avg}(v)$ for all users
2. Compute $\text{sim}(u,v)$ for all users for which there is some intersection with u
3. Compute $\text{score}(u,i)$ for all items that u has not seen yet

$$\text{sim}(u, v) = \frac{\sum_{i \in I_{u,v}} (u_i - \hat{u}) \cdot (v_i - \hat{v})}{\sqrt{\sum_{i \in I_{u,v}} (u_i - \hat{u})^2 \cdot \sum_{i \in I_{u,v}} (v_i - \hat{v})^2}}$$

$$\text{score}(u, i) = \hat{u} + \frac{\sum_{v: v_i \neq \text{NULL}} \text{sim}(v, u) \cdot (v_i - \hat{v})}{\sum_{v: I_{u,v} \neq \emptyset} |\text{sim}(v, u)|}$$

You can do the same with items!

- Item-based similarities with ratings

$$\text{sim}(i, j) = \frac{\sum_{u \in I_{i,j}} (u_i - \hat{i}) \cdot (u_j - \hat{j})}{\sqrt{\sum_{u \in I_{i,j}} (u_i - \hat{i})^2 \cdot \sum_{u \in I_{i,j}} (u_j - \hat{j})^2}}$$

- Item-based recommendations

$$\text{score}(u, i) = \hat{i} + \frac{\sum_{j: u_j \neq \text{NULL}} \text{sim}(i, j) \cdot (u_j - \hat{j})}{\sum_{j: I_{i,j} \neq \emptyset} |\text{sim}(i, j)|}$$

Try it!

| |  |  |  |  |  |  |
|--|---|---|---|---|---|---|
|  | 2 | | | 4 | 5 | |
|  | 5 | | 4 | | | 1 |
|  | | | 5 | | 2 | |
|  | | 1 | | 5 | | 4 |
|  | | | 4 | | | 2 |
|  | 4 | 5 | | 1 | | |

1. Compute $\text{avg}(j)$ for all items
2. Compute $\text{sim}(i, j)$ for all items for which there is some intersection with i
3. Compute $\text{score}(u, i)$ for all users who have not seen i yet

$$\text{sim}(i, j) = \frac{\sum_{u \in I_{i,j}} (u_i - \hat{i}) \cdot (u_j - \hat{j})}{\sqrt{\sum_{u \in I_{i,j}} (u_i - \hat{i})^2 \cdot \sum_{u \in I_{i,j}} (u_j - \hat{j})^2}}$$

$$\text{score}(u, i) = \hat{i} + \frac{\sum_{j: u_j \neq \text{NULL}} \text{sim}(i, j) \cdot (u_j - \hat{j})}{\sum_{j: I_{i,j} \neq \emptyset} |\text{sim}(i, j)|}$$

Note

- There are many ways of computing user-based similarity and item-based similarity
- There are many ways of using these to generate recommendations
- The method we have described is aware of the **bias of users**, in the sense of some users being more positive/negative than others in general

Graph- and clustering-based methods

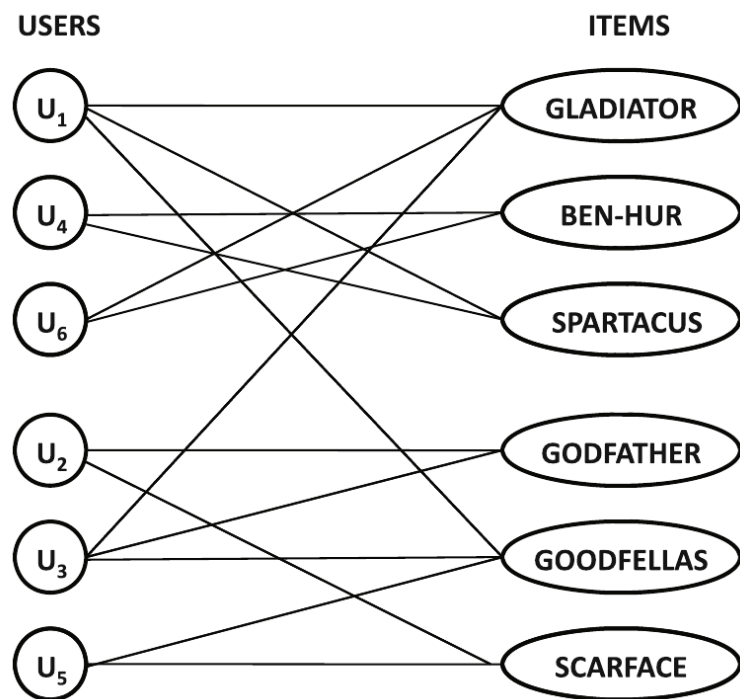

Graph-based methods

- Bipartite user-item graph with nodes $N_u \cup N_i$
- N_u users
- N_i items
- Non-zero utility \Rightarrow edge

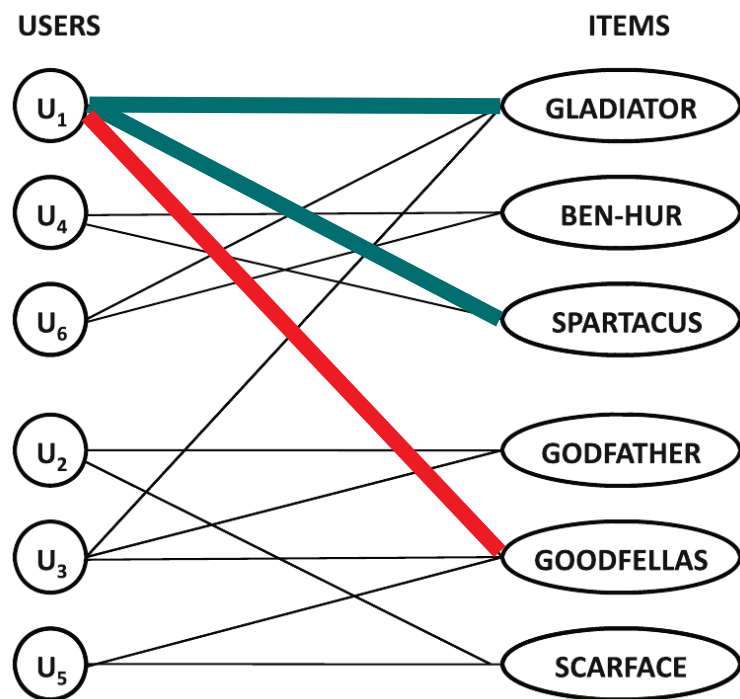

Graph-based methods (cont.)

- Use graph-based methods
 - Random walk with restart to a user or item
 - SimRank
- Low “random jump” probability might favor popular items

Graph-based methods (cont.)

- Signed networks can be used
 - Remember we must interpret ratings with respect to user and item averages
 - Below average rating $\Rightarrow -$
 - Above average rating $\Rightarrow +$
- Positive link prediction problem

Clustering methods

- Motivations
 - Reduce computational cost
 - To some extent address data sparsity
- Results of clustering
 - Clusters of users for user-user similarity recs.
 - Clusters of items for item-item similarity recs.

Clustering methods (cont.)

- User-user recommendation approach
 - Cluster users into groups
 - For any user u , compute average normalized rating for each item i the user has not seen
 - Report these ratings for (u,i)
- Same with item-item recommendations
- Neighborhoods will be smaller

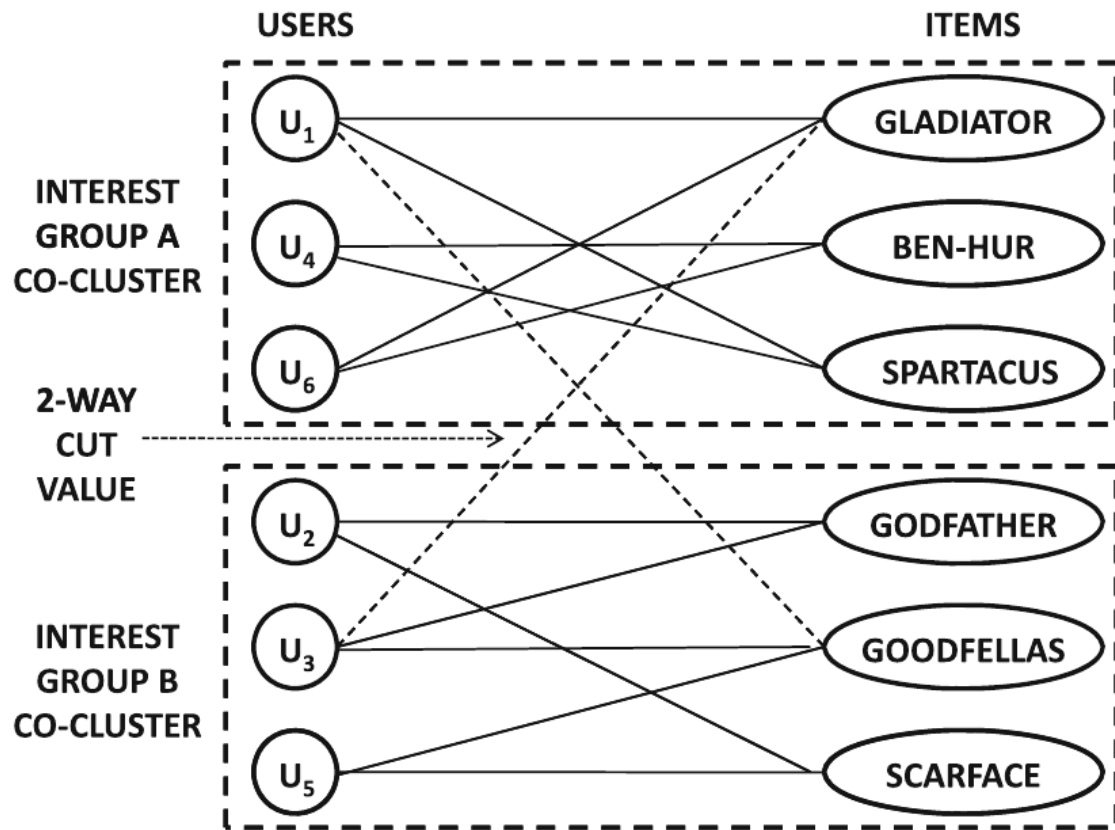

Co-Clustering Approach

INTEREST GROUP A CO-CLUSTER

| | GLADIATOR | BEN-HUR | SPARTACUS | GODFATHER | GOODFELLAS | SCARFACE |
|-------|-----------|---------|-----------|-----------|------------|----------|
| U_1 | 1 | | 1 | | 1 | |
| U_4 | | 1 | 1 | | | |
| U_6 | 1 | 1 | | | | |
| U_2 | | | | 1 | | 1 |
| U_3 | 1 | | | 1 | 1 | |
| U_5 | | | | | 1 | 1 |

INTEREST GROUP B CO-CLUSTER

(a) Co-cluster

(b) User-item graph

Latent factor models

Key idea

- Summarize the correlations across rows and columns in the form of lower dimensional vectors, or **latent** factors
- These latent factors become **hidden** variables that encode the correlations in the data matrix in a concise way and can be used to make **predictions**
- Estimation of the k-dimensional dominant latent factors is often possible even from **incompletely** specified data

Modeling

- n users: $\overline{U}_1, \dots, \overline{U}_n \in \mathbb{R}^k$

- d items: $\overline{I}_1, \dots, \overline{I}_d \in \mathbb{R}^k$

- Approximate rating r_{ij} by

$$r_{ij} \approx \langle \overline{U}_i, \overline{I}_j \rangle = \overline{U}_i^T \overline{I}_j = \overline{I}_j^T \overline{U}_i$$

- Approximate rating matrix $D = [r_{ij}]_{n \times d}$

$$D \approx F_{\text{user}} F_{\text{item}}^T$$

$$F_{\text{user}} \in \mathbb{R}^{n \times k}$$

$$F_{\text{item}} \in \mathbb{R}^{d \times k}$$

Singular Value Decomposition

- SVD $D = Q\Sigma P^T$ $Q^T Q = I, P^T P = I$
 $D \in \mathbb{R}^{n \times d}$
 $\Sigma = \text{diag}(\sigma_1, \dots, \sigma_d) \in \mathbb{R}^{d \times d}, \sigma_1 \geq \dots \geq \sigma_d$
- Truncated SVD $D \approx Q_k \Sigma_k P_k^T$
 $\Sigma_k = \text{diag}(\sigma_1, \dots, \sigma_k) \in \mathbb{R}^{k \times k}, \sigma_1 \geq \dots \geq \sigma_k$
- Note: SVD is undefined for incomplete matrices

Matrix factorization

- SVD is a special form of matrix factorization

$$D \approx UV^T$$

- Objective when D is fully observed

$$\min \|D - UV^T\|_F^2$$

$$\|A\|_F = \sqrt{\sum_{i,j} a_{ij}^2}$$

- Objective when D is partially observed

$$\min \sum_{(i,j) \in \Omega} \left(D_{ij} - \overline{U}_i^T \overline{V}_j \right)^2$$

Ω is the set of observed cells

Non-negative, regularized matrix factorization

- Matrix factorization $D \approx UV^T$

Objective:

$$\min \sum_{(i,j) \in \Omega} \left(D_{ij} - \overline{U}_i^T \overline{V}_j \right)^2 + \lambda \left(\|U\|_F^2 + \|V\|_F^2 \right)$$

Ω is the set of observed cells in the matrix

$$U \geq 0, V \geq 0$$

Example 1: grocery shopping

Example: grocery shopping

| | John | Alice | Mary | Greg | Peter | Jennifer |
|-------------------|------|-------|------|------|-------|----------|
| Vegetables | 0 | 1 | 0 | 1 | 2 | 2 |
| Fruits | 2 | 3 | 1 | 1 | 2 | 2 |
| Sweets | 1 | 1 | 1 | 0 | 1 | 1 |
| Bread | 0 | 2 | 3 | 4 | 1 | 1 |
| Coffee | 0 | 0 | 0 | 0 | 1 | 0 |

- This purchase history indicates the number of time each person has purchased an item
- For clarity we're dealing with categories of items, but they can be the items themselves

In Python

Python code

| | John | Alice | Mary | Greg | Peter | Jennifer |
|------------|------|-------|------|------|-------|----------|
| Vegetables | 0 | 1 | 0 | 1 | 2 | 2 |
| Fruits | 2 | 3 | 1 | 1 | 2 | 2 |
| Sweets | 1 | 1 | 1 | 0 | 1 | 1 |
| Bread | 0 | 2 | 3 | 4 | 1 | 1 |
| Coffee | 0 | 0 | 0 | 0 | 1 | 0 |

```
V = np.array(  
    [[0,1,0,1,2,2],  
     [2,3,1,1,2,2],  
     [1,1,1,0,1,1],  
     [0,2,3,4,1,1],  
     [0,0,0,0,1,0]])
```

```
V = pd.DataFrame(V, columns=['John', 'Alice',  
                             'Mary', 'Greg', 'Peter', 'Jennifer'])
```

```
V.index = ['Vegetables', 'Fruits', 'Sweets',  
           'Bread', 'Coffee']
```

Matrix factorization ($V \approx WH$)

Matrix W (items x factors) with possible names for each factor added for legibility

| | Fruits pickers | Bread eaters | Veggies |
|------------|----------------|--------------|---------|
| Vegetables | 0.00 | 0.04 | 2.74 |
| Fruits | 1.93 | 0.15 | 0.47 |
| Sweets | 0.97 | 0.00 | 0.00 |
| Bread | 0.00 | 2.66 | 1.18 |
| Coffee | 0.00 | 0.00 | 0.59 |

Python code

```
from sklearn.decomposition
import NMF
nmf = NMF(3)
nmf.fit(V)

H =
pd.DataFrame(np.round(nmf.components_,2), columns=V.columns)
H.index = ['Fruits pickers',
'Bread eaters', 'Veggies']

W =
pd.DataFrame(np.round(nmf.transform(V),2), columns=H.index)
W.index = V.index
```

Matrix W (items x factors)

| | Fruits pickers | Bread eaters | Veggies |
|------------|----------------|--------------|---------|
| Vegetables | 0.00 | 0.04 | 2.74 |
| Fruits | 1.93 | 0.15 | 0.47 |
| Sweets | 0.97 | 0.00 | 0.00 |
| Bread | 0.00 | 2.66 | 1.18 |
| Coffee | 0.00 | 0.00 | 0.59 |

Possible names for each factor added for legibility

Matrix H (factors x people)

| | John | Alice | Mary | Greg | Peter | Jennifer |
|----------------|------|-------|------|------|-------|----------|
| Fruits pickers | 1.04 | 1.34 | 0.55 | 0.26 | 0.89 | 0.90 |
| Bread eaters | 0.00 | 0.60 | 1.12 | 1.36 | 0.03 | 0.07 |
| Veggies | 0.00 | 0.35 | 0.00 | 0.34 | 0.77 | 0.69 |

Reconstruction

If you were to recommend one product to someone, what would you recommend and to whom?

Evaluation

Direct evaluation

- Randomized controlled experiment
 - Renamed A/B testing for ... reasons
 - People are split randomly in control/experimental
 - Control group: receives one type of recommendation
 - Experimental group: receives another type
- Metrics such as CTR, retention, etc.
- Requires infrastructure, users, policies

Evaluating with existing data

| | | | | | | |
|--|--|--|--|--|--|--|
| | | | | | | |
| | | | | | | |
| | | | | | | |
| | | | | | | |
| | | | | | | |
| | | | | | | |
| | | | | | | |
| | | | | | | |
| | | | | | | |
| | | | | | | |

Evaluating with existing data

Diagram illustrating a matrix of user ratings for movies, used for evaluation. The matrix is labeled **users** (vertical axis) and **movies** (horizontal axis).

The matrix is divided into two sections:

- Training Data (Yellow cells):** Contains known ratings for users 1, 2, and 3 across movies 1, 2, 3, 4, 5, and 6.
- Test Data Set (Gray cells):** Contains unknown ratings (marked with '?') for users 2, 3, and 4 across movies 4, 5, and 6.

An arrow points from the label **Test Data Set** to the gray cells.

| | | | | | | |
|---|---|---|---|---|---|---|
| | 1 | 3 | 4 | | | |
| | | 3 | 5 | | | 5 |
| | | | 4 | 5 | | 5 |
| | | | 3 | | | |
| | | | 3 | | | |
| 2 | 2 | | | ? | | ? |
| | | | | | ? | |
| | | 2 | 1 | | | ? |
| | | 3 | | | ? | |
| 1 | 1 | | | | | |

Evaluation metrics

- RMSE (root of mean of squared errors)

$$\sqrt{E[(x - \hat{x})^2]}$$

- Precision @ k
 - % of recommendations that are correct among those in the top k positions
- Rank correlation
 - Spearman's correlation between system and user

Evaluating is hard

- Accuracy is not all
- We also want diversity
- We want to be contextually sensitive
- The order of predictions matters
- RMSE might penalize a method that does well for high ratings but bad for others

Example 2: Netflix prize

Example 2: Netflix prize (2009)

- Netflix offered \$1,000,000 to anyone beating their algorithm by 10% in **RMSE**
- Provided 100M (user,movie) ratings for training
- Held a testing set and allowed one guess/day on the testing set to create a leader board

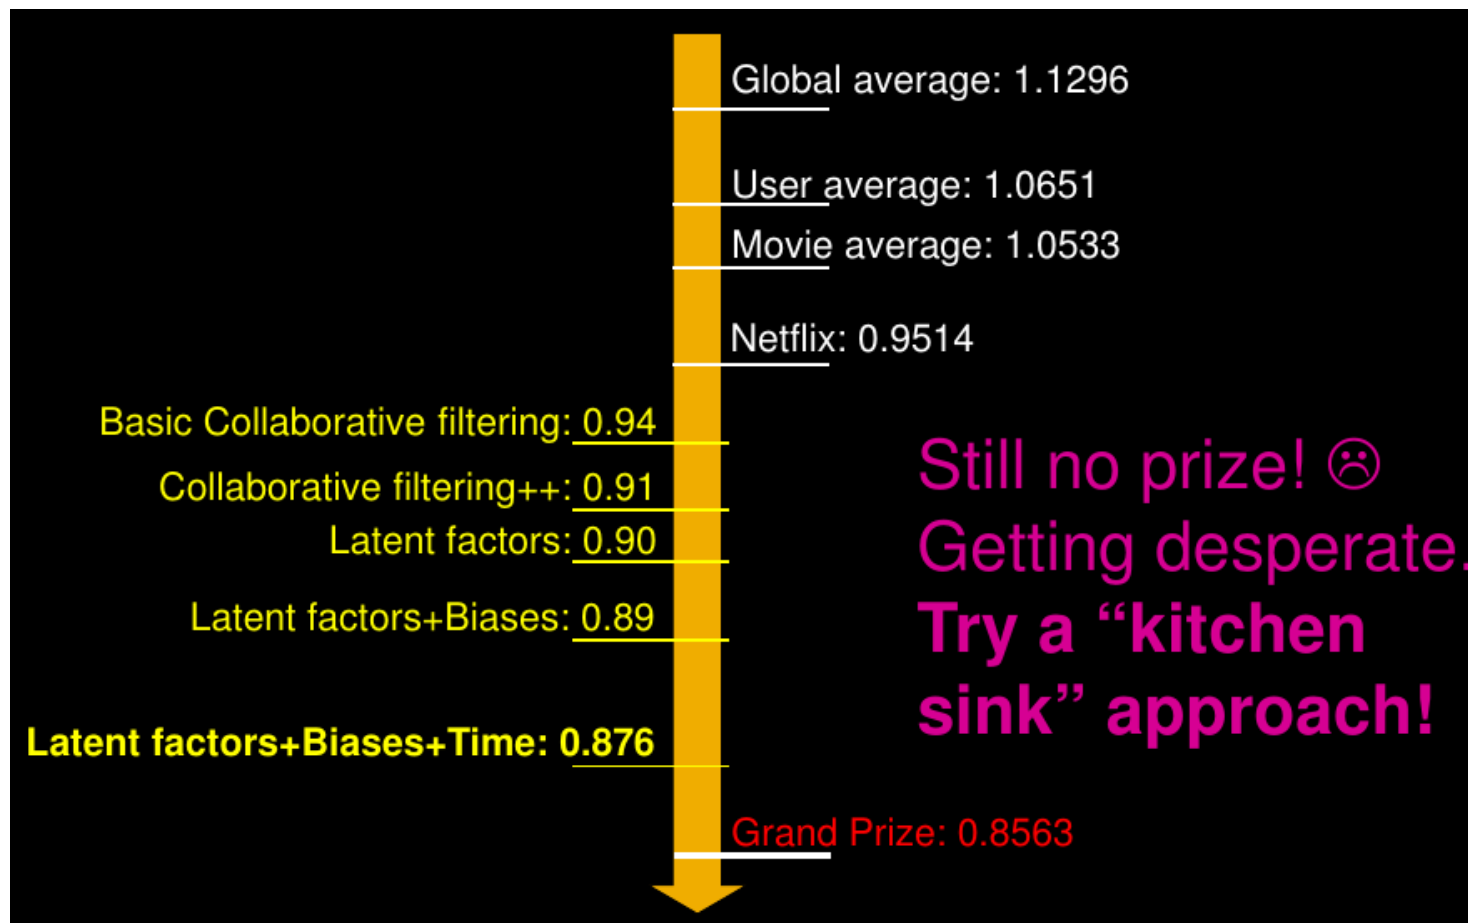

| Rank | Team Name | Best Score | % Improvement | Last Submit Time |
|--|---|------------|---------------|---------------------|
| 1 | BellKor's Pragmatic Chaos | 0.8558 | 10.05 | 2009-06-26 18:42:37 |
| Grand Prize - RMSE <= 0.8563 | | | | |
